Management Information Base for Frame Relay DTEs Using SMIv2

1. Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

2. Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in TCP/IP- based internets. In particular, it defines objects for managing Frame Relay interfaces on DTEs.

3. The SNMPv2 Network Management Framework

The major components of the SNMPv2 Network Management framework are described in the documents listed below.

- RFC 1902 [1] defines the Structure of Management Information (SMI), the mechanisms used for describing and naming objects for the purpose of management.
- STD 17, RFC 1213 [2] defines MIB-II, the core set of managed objects (MO) for the Internet suite of protocols.
- RFC 1905 [3] defines the protocol used for network access to managed objects.

The framework is adaptable/extensible by defining new MIBs to suit the requirements of specific applications/protocols/situations.

Managed objects are accessed via a virtual information store, the MIB. Objects in the MIB are defined using the subset of Abstract Syntax Notation One (ASN.1) defined in the SMI. In particular, each object type is named by an OBJECT IDENTIFIER, which is an administratively assigned name. The object type together with an object instance serves to uniquely identify a specific instantiation of the object. For human convenience, often a textual string, termed the descriptor, is used to refer to the object type.

4. Overview

4.1. Frame Relay Operational Model

For the purposes of understanding this document, Frame Relay is viewed as a multi-access media, not as a group of point- to-point connections. This model proposes that Frame Relay is a single interface to the network (physical connection) with many destinations or neighbors (virtual connections). This view enables a network manager the ability to group all virtual connections with their corresponding physical connection thereby allowing simpler diagnostics and trouble shooting.

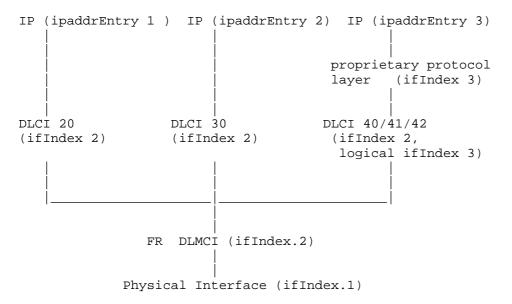

With the extension of the interfaces MIB, it is possible to configure frame relay DLCs as individual interfaces and create ifTable entries for each. This is not recommended and is not directly supported by this MIB. Additionally, in the presence of demand circuits creation of individual ifEntries for each is not possible.

Brown & Baker

Standards Track

[Page 2]

Should the user wish to group DLCs together to associate them with a higher layer, or to associate a DLC with an unnumbered point-to-point service, the frame relay DTE MIB provides an entry in the frCircuitEntry record. For example, suppose one were to configure a company proprietary protocol to run above several of the frame relay VCs. The basic layering would look something like the following:

A configuration which specified that DLCI 40, 41, and 42 were associated with a proprietary protocol layer, while DLCI 20 and 30 were to run IP directly can now be expressed using a combination of frCircuitIfIndex and frCircuitLogicalIfIndex. In this particular case DLCIs 40, 41 and 42 would use frCircuitIfIndex equal to the frame relay interface level (2) while their frCircuitLogicalIfIndex would indicate the proprietary protocol (3). DLCIs 20 and 30 would have both instances set to the frame relay interface (2).

Object	Meaning for Frame Relay Interface
ifDescr ifType	As per DESCRIPTION in RFC 1573. The value allocated for Frame Relay Interfaces - frameRelay (32).
ifMtu	Set to maximum frame size in octets for this frame relay interface.

Brown & Baker Standards Track [Page 3]

- ifSpeed The access rate for the frame relay interface. This could be different from the speed of the underlying physical interface, e.g. in a fractional T1 case the access rate could be 384 kbits/s (the value reported in this object) whereas the speed of the underlying interface would be 1.544 Mbits/s (the value reported in the instance of ifSpeed for the ifEntry with type ds1).
- ifPhysAddress The primary address for this interface assigned by the Frame Relay interface provider. An octet string of zero length if no address is used for this interface.
- ifAdminStatus As per DESCRIPTION in RFC 1573.

ifOperStatus As per DESCRIPTION in RFC 1573.

- ifLastChange As per DESCRIPTION in RFC 1573.
- ifInOctets The number of received octets. This includes not only the information field (user data) but also the frame relay header and CRC.
- ifInUcastPkts The number of frames received on nonmulticast DLCIs
- ifInDiscards The number of frames that were successfully received but were discarded because of format errors or because the VC was not known. Format errors, in this case, are any errors which would prevent the system from recognizing the DLCI and placing the error in the frCircuitDiscard category.
- ifInErrors The number of received frames that are discarded, because of an error. Possible errors can be the following: the frame relay frames were too long or were too short, the frames had an invalid or unrecognized DLCI values, or incorrect header values.

Brown & Baker

Standards Track

[Page 4]

ifInUnknownProtos Number of unknown or unsupported upper layer protocol frames received and discarded. The number of received octets. This ifOutOctets includes not only the information field (user data) but also the frame relay header and CRC. ifOutUcastpkts The number of frames sent. ifOutDiscards The number of frames discarded in the transmit direction. The number of frames discarded in the ifOutErrors egress direction, because of errors. ifName As per DESCRIPTION in RFC 1573. ifInMulticastPkts The number of unerrored frames received on a multicast DLCI. ifInBroadcastPkts Always zero (0) as there are no broadcast frames. ifOutMulticastPkts The number of frames transmitted over a multicast DLCI. ifOutBroadcastPkts Always zero (0) as there are no broadcast frames. ifHCInOctets Only required when ifSpeed >= 155 Mbits/s. See details for ifInOctets. ifHCOutOctets Only required when ifSpeed >= 155 Mbits/s. See details for ifInOctets. ifLinkUpDownTrapEnble As per DESCRIPTION in RFC 1573. ifHighSpeed The access rate of the frame relay interface measured in Mbits/s. If the access rate is less than 1 Mbits/s, this object returns 0. ifPromiscuousMode Set to false(2). ifConnectorPresent Set to false(2).

Brown & Baker Standards Track [Page 5]

4.2. Textual Conventions

One new data type is introduced as a textual convention in this MIB document. This textual convention enhances the readability of the specification and can ease comparison with other specifications if appropriate. It should be noted that the introduction of this textual conventions has no effect on either the syntax nor the semantics of any managed objects. The use of this is merely an artifact of the explanatory method used. Objects defined in terms of one of these methods are always encoded by means of the rules that define the primitive type. Hence, no changes to the SMI or the SNMP are necessary to accommodate this textual conventions which is adopted merely for the convenience of readers and writers in pursuit of the elusive goal of clear, concise, and unambiguous MIB documents.

The new data type is DLCI. DLCI refers to the range 0..DLCINumber, and is used to refer to the valid Data Link Connection Indices. DLCINumber is, by definition, the largest possible DLCI value possible under the configured Q.922 Address Format.

4.3. Structure of MIB

The MIB is composed of three groups, one defining the Data Link Connection Management Interface (DLCMI), one describing the Circuits, and a third describing errors.

During normal operation, Frame Relay virtual circuits will be added, deleted and change availability. The occurrence of such changes is of interest to the network manager and therefore, one trap is defined, intended to be corollary to the SNMP "Link Up" and "Link Down" traps.

5. Changes from RFC 1315

Below are listed the changes from the previously published version this document, which was RFC 1315:

- o The MIB module was converted from SMIv1 to SMIv2 format. Note: due to this, the table indices have access of "read-only" instead of "not-accessible", which is the typical value for index objects in SMIv2.
- o The module name was changed from RFC1315-MIB to FRAME-RELAY-DTE-MIB.
- o The textual convention "Index" was dropped from the MIB module and "InterfaceIndex" from the interfaces MIB module, IF-MIB, was used in its place.

Brown & Baker

Standards Track

[Page 6]

- Objects frDlcmiStatus and frDlcmiRowStatus were added to table frDlcmiTable.
- o Added values "itut933A(5)" (from CCITT Q933 Annex A) and "ansiT1617D1994(6)" (from ANSI T1.617a-1994 Annex D) to the enumerations for object frDlcmiState.
- The labels for the enumerated values for object frDlcmiAddressLen were renamed to remove their hyphens as required by SMIv2.
- Added clarification that the "management virtual circuit" (i.e. DLCI 0) is a member of the circuit table.
- o Added the following objects to table frCircuitTable: frCircuitMulticast, frCircuitType, frCircuitDiscards, frCircuitReceivedDEs, frCircuitSentDEs, frCircuitLogicalIfIndex, and frCircuitRowStatus.
- The definition of object frCircuitReceivedOctets was clarified as to which octets were counted.
- Added the objects frErrFaults and frErrFaultTime to table frErrTable.
- o Added clarification to the values of object frErrType.
- Added size on definition of object frErrData and clarified what data to capture.
- o Changed identififier for OID value { frameDelayDTE 4 }
 from frame-relay-globals to frameRelayTrapControl.
- o Added object frTrapMaxRate.
- Created object groups frPortGroup, frCircuitGroup, frTrapGroup, frErrGroup, frPortGroup0, frCircuitGroup0, frTrapGroup0, and frErrGroup0.
- o Created notification group frNotificationGroup.
- Created module compliances frCompliance and frCompliance0.
- Added ranges to objects frCircuitCommittedBurst, frCircuitExcessBurst, and frCircuitThroughput.

A Frame Relay service is a multiplexing service. Data
Link Connection Identifiers enumerate virtual circuits
(permanent or dynamic) which are layered onto the underlying
circuit, represented by ifEntry. Therefore, each of the entries
in the Standard MIB's Interface Table with an IfType of
Frame Relay represents a Q.922 interface. Zero or more
virtual circuits are layered onto this interface and provide
interconnection with various remote destinations.
Each such virtual circuit is represented by an entry in the
circuit table. The management virtual circuit (i.e. DLCI 0)
is a virtual circuit by this definition and will be represented
with an entry in the circuit table.

7. Security Issues

Security issues for this MIB are entirely covered by the SNMP Security Architecture, and have not been expanded within the contents of this MIB.

8. Acknowledgments

This document was originally produced by the IP Over Large Public Data Networks (IPLPDN) Working Group, and has since been carried on in the PPP Working Group, sort of. Currently, the Ion Working Group is its host.

Special thanks to James Watt of Newbridge Networks for his fine suggestions and pastable text.
