Event MIB

Status of this Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Copyright Notice

Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in the Internet community. In particular, it describes managed objects that can be used to manage and monitor MIB objects and take action through events.

The Event MIB provides the ability to monitor MIB objects on the local system or on a remote system and take simple action when a trigger condition is met.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119.

1. The SNMP Management Framework

The SNMP Management Framework presently consists of five major components:

- o An overall architecture, described in RFC 2571 [RFC2571].
- Mechanisms for describing and naming objects and events for the purpose of management. The first version of this Structure of Management Information (SMI) is called SMIv1 and described in STD 16, RFC 1155 [RFC1155], STD 16, RFC 1212 [RFC1212] and RFC 1215 [RFC1215]. The second version, called SMIv2, is described in STD 58, RFC 2578 [RFC2578], STD 58, RFC 2579 [RFC2579] and STD 58, RFC 2580 [RFC2580].
- Message protocols for transferring management information. The first version of the SNMP message protocol is called SNMPv1 and described in STD 15, RFC 1157 [RFC1157]. A second version of the SNMP message protocol, which is not an Internet standards track protocol, is called SNMPv2c and described in RFC 1901 [RFC1901] and RFC 1906 [RFC1906]. The third version of the message protocol is called SNMPv3 and described in RFC 1906 [RFC1906], RFC 2572 [RFC2572] and RFC 2574 [RFC2574].
- Protocol operations for accessing management information. The first set of protocol operations and associated PDU formats is described in STD 15, RFC 1157 [RFC1157]. A second set of protocol operations and associated PDU formats is described in RFC 1905 [RFC1905].
- A set of fundamental applications described in RFC 2573
 [RFC2573] and the view-based access control mechanism described in RFC 2575 [RFC2575].

A more detailed introduction to the current SNMP Management Framework can be found in RFC 2570 [RFC2570].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the mechanisms defined in the SMI.

Kavasseri & Stewart

Standards Track

[Page 2]

This memo specifies a MIB module that is compliant to the SMIv2. A MIB conforming to the SMIv1 can be produced through the appropriate translations. The resulting translated MIB must be semantically equivalent, except where objects or events are omitted because no translation is possible (use of Counter64). Some machine readable information in SMIv2 will be converted into textual descriptions in SMIv1 during the translation process. However, this loss of machine readable information is not considered to change the semantics of the MIB. It may not be possible to meaningfully monitor Counter64 objects using an SMIv1 version of the MIB.

2. Overview

With network sizes well beyond the ability of people to manage them directly, automated, distributed management is vital. An important aspect of such management is the ability of a system to monitor itself or for some other system to monitor it.

The Event MIB provides the ability to monitor MIB objects on the local system or on a remote system and take simple action when a trigger condition is met.

The MIB is intended to suit either a relatively powerful manager or mid-level manager, as well as a somewhat more limited self-managing system.

3. Relationship to Other MIBs

The Event MIB is based on extensive experience with the RMON MIB [RFC1757] and provides a superset of the capabilities of the RMON alarm and event groups. Conceptually, the key extension is the ability to allow alarms to be generated for MIB objects that are on another network element. The Event MIB calls "triggers" what the RMON MIB called "alarms," but the concepts are the same. Event MIB triggers maintain the RMON handling of thresholds and add the concept of booleans. Event MIB events maintain the RMON concept of sending an SNMP notification in response to a trigger and add the concept of setting a MIB object.

The Event MIB is the successor and update to SNMPv2's Manager-to-Manager MIB [RFC1451] which was declared Historic pending this work.

The Event MIB depends on the services of the SNMPv3 Management Target and Notification MIBs [RFC2573].

The Event MIB is nicely complemented by the Distributed Management Expression MIB [RFC2982], which is the expected source of boolean objects to monitor. Note that there is considerable overlap between

Kavasseri & Stewart

Standards Track

[Page 3]

the wildcard and delta sample capabilities of the Event and Expression MIBs. A carefully-planned implementation might well use common code to provide the overlapping functions.

4. MIB Sections

The MIB has four sections: triggers, objects, events, and notifications. Triggers define the conditions that lead to events. Events may cause notifications.

The trigger table lists what objects are to be monitored and how and relates each trigger to an event. It has supplementary, companion tables for additional objects that depend on the type of test done for the trigger.

The objects table lists objects that can be added to notifications based on the trigger, the trigger test type, or the event that resulted in the notification.

The event table defines what happens when an event is triggered: sending a notification, setting a MIB object or both. It has supplementary, companion tables for additional objects that depend on the action taken.

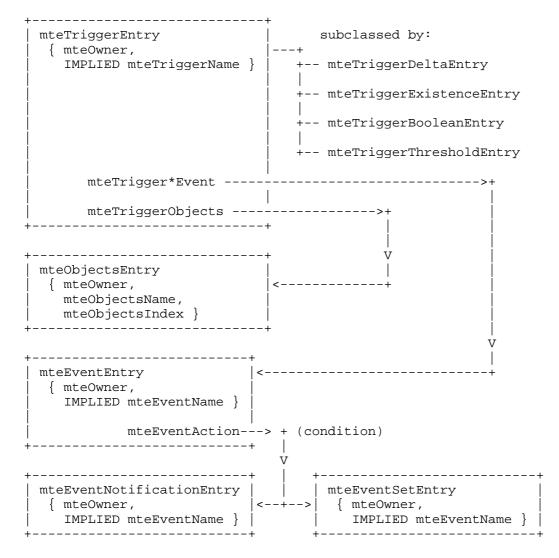

The notification section defines a set of generic notifications to go with the events and for Event MIB error handling, and it defines a set of objects to put in those notifications.

The following diagram describes the relationships between the tables in the Event MIB.

Kavasseri & Stewart

Standards Track

[Page 4]

5. Operation

The Event MIB is instrumentation for a distributed management application that monitors MIB objects. In its simplest form this application monitors individual, local MIB objects, just as an RMON probe fulfills the functions implied by RMON's alarm and event operation. Additionally the application can monitor remote objects and wildcarded groups of objects.

Kavasseri & Stewart Standards Track

[Page 5]

Remote monitoring uses the tag service of the Management Target MIB [RFC2573] to select and access remote systems as an ordinary SNMPbased management application. Local monitoring may be via a more intimate, local interface which may, for example, bypass SNMP encoding but otherwise is functionally identical to remote SNMP operation, including the application of access control. A selfmanagement only system MAY not implement remote monitoring.

Wildcards indicate that the application SHOULD use a GetNext-type operation to find the zero or more instances implied by a truncated object identifier, just like an ordinary SNMP-based management application. Each instance of a wildcard is treated as if it were a separate entry, that is the instances of a wildcarded object are independent of one another. For example, a wild-carded object may trigger an event, and result in the setting of another wildcarded object. The instance that satisfied the trigger function is used to perform the set function. All of this takes place independently of any additional instances that may fill the wildcard.

Error handling is by notification. These error notifications SHOULD be enabled only for the diagnosis of problems indicated by error counters. If minimizing the probability of notification loss is a concern they SHOULD be transmitted as Inform PDUs as described in the [SNMP-TARGET-MIB] or directed to a log as described in the Notification Log MIB [rfcNotificationLogMIB]. Note that this does not mean the Notification Log MIB is REQUIRED, since in fact notifications usually are not lost, but that the Notification Log MIB can be helpful with this as well as other MIBs that include notifications.

Although like most MIBs this one has no explicit controls for the persistence of the values set in configuring events, a robust, polite implementation would certainly not force its managing applications to reconfigure it whenever it resets.

Again, as with most MIBs, it is implementation-specific how a system provides and manages such persistence. To speculate, one could imagine, for example, that persistence depended on the context in which the expression was configured, or perhaps system-specific characteristics of the expression's owner. Or perhaps everything in a MIB such as this one, which is clearly aimed at persistent configuration, is automatically part of a system's other persistent configuration.

Kavasseri & Stewart

Standards Track

[Page 6]

6. Security

Security of Event MIB entries depends on SNMPv3 access control for the entire MIB or for subsets based on entry owner names.

Security of monitored objects for remote access depends on the Management Target MIB [RFC2573]. Security for local access can depend on the Management Target MIB or on recording appropriate security credentials of the creator of an entry and using those to access the local objects. These security credentials are the parameters necessary as inputs to isAccessAllowed from the Architecture for Describing SNMP Management Frameworks. When accessing local objects without using a local target tag, the system MUST (conceptually) use isAccessAllowed to ensure that it does not violate security.

To facilitate the provisioning of access control by a security administrator for this MIB itself using the View-Based Access Control Model (VACM) defined in RFC 2275 [RFC2575] for tables in which multiple users may need to independently create or modify entries, the initial index is used as an "owner index". Such an initial index has a syntax of SnmpAdminString, and can thus be trivially mapped to a securityName or groupName as defined in VACM, in accordance with a security policy.

If a security administrator were to employ such an approach, all entries in related tables belonging to a particular user will have the same value for this initial index. For a given user's entries in a particular table, the object identifiers for the information in these entries will have the same sub-identifiers (except for the "column" sub-identifier) up to the end of the encoded owner index. To configure VACM to permit access to this portion of the table, one would create vacmViewTreeFamilyTable entries with the value of vacmViewTreeFamilySubtree including the owner index portion, and vacmViewTreeFamilyMask "wildcarding" the column sub-identifier. More elaborate configurations are possible.

DEFVAL { ''H } ::= { mteTriggerEntry 3 } mteTriggerTest OBJECT-TYPE SYNTAX BITS { existence(0), boolean(1), threshold(2) } MAX-ACCESS read-create STATUS current DESCRIPTION "The type of trigger test to perform. For 'boolean' and 'threshold' tests, the object at mteTriggerValueID MUST evaluate to an integer, that is, anything that ends up encoded for transmission (that is, in BER, not ASN.1) as an integer. For 'existence', the specific test is as selected by mteTriggerExistenceTest. When an object appears, vanishes or changes value, the trigger fires. If the object's appearance caused the trigger firing, the object MUST vanish before the trigger can be fired again for it, and vice versa. If the trigger fired due to a change in the object's value, it will be fired again on every successive value change for that object. For 'boolean', the specific test is as selected by mteTriggerBooleanTest. If the test result is true the trigger fires. The trigger will not fire again until the value has become false and come back to true. For 'threshold' the test works as described below for

Kavasseri & Stewart

Standards Track

[Page 13]

mteTriggerThresholdStartup, mteTriggerThresholdRising, and mteTriggerThresholdFalling. Note that combining 'boolean' and 'threshold' tests on the same object may be somewhat redundant." DEFVAL { { boolean } } ::= { mteTriggerEntry 4 } mteTriggerSampleType OBJECT-TYPE INTEGER { absoluteValue(1), deltaValue(2) } SYNTAX MAX-ACCESS read-create STATUS current DESCRIPTION "The type of sampling to perform. An 'absoluteValue' sample requires only a single sample to be meaningful, and is exactly the value of the object at mteTriggerValueID at the sample time. A 'deltaValue' requires two samples to be meaningful and is thus not available for testing until the second and subsequent samples after the object at mteTriggerValueID is first found to exist. It is the difference between the two samples. For unsigned values it is always positive, based on unsigned arithmetic. For signed values it can be positive or negative. For SNMP counters to be meaningful they should be sampled as a 'deltaValue'. For 'deltaValue' mteTriggerDeltaTable contains further parameters. If only 'existence' is set in mteTriggerTest this object has no meaning." DEFVAL { absoluteValue } ::= { mteTriggerEntry 5 } mteTriggerValueID OBJECT-TYPE SYNTAX OBJECT IDENTIFIER MAX-ACCESS read-create STATUS current DESCRIPTION "The object identifier of the MIB object to sample to see if the trigger should fire. This may be wildcarded by truncating all or part of the instance portion, in which case the value is obtained as if with a GetNext function, checking multiple values

Kavasseri & Stewart

Standards Track

[Page 14]

if they exist. If such wildcarding is applied, mteTriggerValueIDWildcard must be 'true' and if not it must be 'false'. Bad object identifiers or a mismatch between truncating the identifier and the value of mteTriggerValueIDWildcard result in operation as one would expect when providing the wrong identifier to a Get or GetNext operation. The Get will fail or get the wrong object. The GetNext will indeed get whatever is next, proceeding until it runs past the initial part of the identifier and perhaps many unintended objects for confusing results. If the value syntax of those objects is not usable, that results in a 'badType' error that terminates the scan. Each instance that fills the wildcard is independent of any additional instances, that is, wildcarded objects operate as if there were a separate table entry for each instance that fills the wildcard without having to actually predict all possible instances ahead of time." DEFVAL { zeroDotZero } ::= { mteTriggerEntry 6 } mteTriggerValueIDWildcard OBJECT-TYPE TruthValue SYNTAX MAX-ACCESS read-create STATUS current DESCRIPTION "Control for whether mteTriggerValueID is to be treated as fully-specified or wildcarded, with 'true' indicating wildcard." DEFVAL { false } ::= { mteTriggerEntry 7 } mteTriggerTargetTag OBJECT-TYPE SnmpTagValue SYNTAX MAX-ACCESS read-create STATUS current DESCRIPTION "The tag for the target(s) from which to obtain the condition for a trigger check. A length of 0 indicates the local system. In this case, access to the objects indicated by mteTriggerValueID is under the security credentials of the requester that set mteTriggerEntryStatus to 'active'. Those credentials are the input parameters for isAccessAllowed from the Architecture for Describing SNMP Management Frameworks. Otherwise access rights are checked according to the security

Kavasseri & Stewart Standards Track

[Page 15]

parameters resulting from the tag." DEFVAL { ''H } ::= { mteTriggerEntry 8 } mteTriggerContextName OBJECT-TYPE SYNTAX SnmpAdminString MAX-ACCESS read-create STATUS current DESCRIPTION "The management context from which to obtain mteTriggerValueID. This may be wildcarded by leaving characters off the end. For example use 'Repeater' to wildcard to 'Repeater1', 'Repeater2', 'Repeater-999.87b', and so on. To indicate such wildcarding is intended, mteTriggerContextNameWildcard must be 'true'. Each instance that fills the wildcard is independent of any additional instances, that is, wildcarded objects operate as if there were a separate table entry for each instance that fills the wildcard without having to actually predict all possible instances ahead of time. Operation of this feature assumes that the local system has a list of available contexts against which to apply the wildcard. If the objects are being read from the local system, this is clearly the system's own list of contexts. For a remote system a local version of such a list is not defined by any current standard and may not be available, so this function MAY not be supported." DEFVAL { ''H } ::= { mteTriggerEntry 9 } mteTriggerContextNameWildcard OBJECT-TYPE SYNTAX TruthValue MAX-ACCESS read-create STATUS current DESCRIPTION "Control for whether mteTriggerContextName is to be treated as fully-specified or wildcarded, with 'true' indicating wildcard." DEFVAL { false } ::= { mteTriggerEntry 10 } mteTriggerFrequency OBJECT-TYPE SYNTAX Unsigned32 UNITS "seconds" MAX-ACCESS read-create STATUS current

Kavasseri & Stewart

Standards Track

[Page 16]

DESCRIPTION "The number of seconds to wait between trigger samples. То encourage consistency in sampling, the interval is measured from the beginning of one check to the beginning of the next and the timer is restarted immediately when it expires, not when the check completes. If the next sample begins before the previous one completed the system may either attempt to make the check or treat this as an error condition with the error 'sampleOverrun'. A frequency of 0 indicates instantaneous recognition of the condition. This is not possible in many cases, but may be supported in cases where it makes sense and the system is able to do so. This feature allows the MIB to be used in implementations where such interrupt-driven behavior is possible and is not likely to be supported for all MIB objects even then since such sampling generally has to be tightly integrated into low-level code. Systems that can support this SHOULD document those cases where it can be used. In cases where it can not, setting this object to 0 should be disallowed." DEFVAL $\{600\}$::= { mteTriggerEntry 11 } mteTriggerObjectsOwner OBJECT-TYPE SYNTAX SnmpAdminString (SIZE (0..32)) MAX-ACCESS read-create STATUS current DESCRIPTION "To go with mteTriggerObjects, the mteOwner of a group of objects from mteObjectsTable."               OBJECT IDENTIFIER
    SYNTAX
   MAX-ACCESS read-write
   STATUS
             current
   DESCRIPTION
        "The OBJECT IDENTIFIER (OID) of a TimeTicks, TimeStamp, or
       DateAndTime object that indicates a discontinuity in the value
       at mteTriggerValueID.
       The OID may be for a leaf object (e.g. sysUpTime.0) or may
       be wildcarded to match mteTriggerValueID.
       This object supports normal checking for a discontinuity in a
        counter. Note that if this object does not point to sysUpTime
       discontinuity checking MUST still check sysUpTime for an overall
       discontinuity.
        If the object identified is not accessible the sample attempt
        is in error, with the error code as from an SNMP request.
       Bad object identifiers or a mismatch between truncating the
        identifier and the value of mteDeltaDiscontinuityIDWildcard
       result in operation as one would expect when providing the
       wrong identifier to a Get operation. The Get will fail or get
       the wrong object. If the value syntax of those objects is not
       usable, that results in an error that terminates the sample
       with a 'badType' error code."

    }
mteEventSetObject OBJECT-TYPE
   SYNTAX OBJECT IDENTIFIER
   MAX-ACCESS read-write
   STATUS current
   DESCRIPTION
        "The object identifier from the MIB object to set if
       mteEventActions has 'set' set.
       This object identifier may be wildcarded by leaving
        sub-identifiers off the end, in which case
       nteEventSetObjectWildCard must be 'true'.
       If mteEventSetObject is wildcarded the instance used to set the
       object to which it points is the same as the instance from the
       value of mteTriggerValueID that triggered the event.
       Each instance that fills the wildcard is independent of any
       additional instances, that is, wildcarded objects operate
       as if there were a separate table entry for each instance
        that fills the wildcard without having to actually predict
       all possible instances ahead of time.
       Bad object identifiers or a mismatch between truncating the
       identifier and the value of mteSetObjectWildcard
       result in operation as one would expect when providing the
       wrong identifier to a Set operation. The Set will fail or set
        the wrong object. If the value syntax of the destination
        object is not correct, the Set fails with the normal SNMP
       error code."
